2007 Michigan Alfalfa Variety Trials Report

Richard Leep¹, Timothy Dietz², Doo-Hong Min³, and Christian Kapp⁴

November 30, 2007

Comments on the 2007 Growing Season

Michigan weather, once again, presented challenges to many producers. Hard frost in mid-April resulted in damage on newly emerged shoots and foliage in established stands and delayed planting activities for several crops statewide. This late frost resulted in lower first cutting yields for most forage producers in Michigan. The south-central portion of the state received excess rainfall in May and early-June, which resulted in increased levels root rot diseases, reduced effectiveness of herbicides, and stand loss in poorly drained areas. Most of the state experienced dry conditions beginning in July and continuing until mid-August. Northern areas of the state received below-average rainfall from late-April to September. The northwest region was the hardest-hit, where for some producers; a single cutting of hay was all that was obtained. Forage variety trial yields were lower than normal statewide. Growing season precipitation amounts are presented for each location in Table 1.

Trial Descriptions

Alfalfa varieties were tested in four locations across the state, using cutting, fertility, and IPM management strategies that are optimal for each location. Alfalfa varieties are planted using a Carter Nursery Seeder in three-ft. wide (5 rows with 6" spacing) by twenty-five ft. long plots into conventionally tilled soil in a randomized complete block design with a minimum of four replications. Irrigation may be used in the seeding year for stand establishment, but subsequent years are supported only by natural rainfall. A pre-incorporated application of EPTC herbicide is normally used for weed control with, if necessary, follow-up applications of Imazamox and/or Sethoxydim for escapes. Phosphorus, Potassium, and Boron fertilizer (0-13-39+0.5% B) is applied according to soil tests the seeding year, and fertilizer applications subsequent years are applied according to the replacement value of one ton of dry alfalfa harvested removing 14 lbs of P and 40 lbs of K per acre. Plots are harvested with a three-foot Carter Flail-type Forage Harvester with sub-samples collected for DM determination. Trials are normally maintained for a total of 4 years (seeding year plus three).

Chatham (46.347°N) and Daggett (45.48°N) in the Upper Peninsula

The Upper Peninsula Experiment Station (Chatham, Alger Co. [location 1]) and Daggett, Menominee Co. are locations for trials established spring of 2005. These areas have colder winters than Lake City (location 2), but more snow. Winterhardiness and persistence are important in the Upper Peninsula. Trials are normally seeded in the

⁴ Research Technician, Upper Peninsula Exp. Sta., Michigan State Univ.

spring, and are usually cut three times per year: Cut 1- June 10-20; Cut 2 – July 15-25 and Cut 3 – end of September. Potato leafhopper (PLH) is not normally a problem, but populations are monitored and controlled if necessary. Below average rainfall was received in the 2007 growing season at Chatham and Daggett. Dry-matter yields for the Daggett and Chatham are presented in Tables 2 and 3.

Lake City (44.35°N) in Central Northern Lower Michigan

Lake City (location 2) is 130 miles north of East Lansing and has colder winters than East Lansing and less snow than Chatham. Both winterhardiness and persistence are important characteristics for alfalfa varieties grown at Lake City. Trials are managed for good yields (4-6 tons/acre) and long stand life. Trials at Lake City are typically cut three times per year: Cut 1 - June 10-20; Cut 2 - July 25 to August 5; Cut 3 - mid to late September. Yield data for 2004, 2005, and 2006 seedings at Lake City are reported in Tables 4, 5, and 6, respectively. The 2007 trial was seeded May 8 and an application of Imazomox with spray-grade AMS was made in June. Data for the 2007 seeding is presented in Table 7.

Saginaw (43.35°N) in East-Central Lower Michigan

The East-Central location is on the Saginaw Experiment Station in Saginaw County on Swan Creek Rd (location 3). Saginaw is located about 90 miles northeast of East Lansing. The soils of this area are lake/river bed soils which are prone to heaving as a result of freeze-thawing cycles. This trial is usually cut four times a year: Cut 1 ~ June 1; Cut 2 ~ July 1; Cut 3 – August 10-15; Cut 4 – October 15-20. This is the final year of data for this location. A total of four cuttings were obtained from this trial and yield data is reported in Table 8.

East Lansing (42.72°N) in Southern Lower Michigan

Alfalfa variety trials are seeded annually at East Lansing in southern lower-Michigan (location 4). These trials are located on the Crop and Soil Sciences Agronomy Farm and are usually seeded in the spring. Trials are managed for high yields (8 tons/acre) using four cuttings per year. Typical cutting dates are: Cut 1 - late May to early June (late bud to early bloom); Cut 2 - July 5-15 (1/10 bloom); Cut 3 - August 5-15 (1/10 bloom); Cut 4 - mid to late October with little regrowth after cutting. High fertility with P and especially K is essential for obtaining high yields. Potato leafhopper (*Empoasca fabae*) are controlled with an application of Cygon (dimethoate) insecticide prior to cut 2 and 3, and Alfalfa weevil (*Hypera posticai*) populations are controlled as needed with Sevin (carbaryl) prior to the first cutting in the standard trials. The Potato leafhopper resistant variety trials

are not treated with insecticides. Imazomox and AMS was applied for weed control of Redroot pigweed (*Amaranthus palmeri*), Common lambsquarter (*Chenopodium album*), and foxtail (*Setaria spp.*) when weeds were approximately 4 inches tall in the seeding year and only as needed in subsequent years. Standard variety trial data is presented in Tables 9, 11, 13, 15 while the Potato leafhopper resistant (PLHR) alfalfa data are in Tables 10, 12, 14 and 16.

Statistics

Data are analyzed using PROC GLM or MIXED in SAS v. 8.2 software (Cary, NC). Means, coefficient of variation (CV%), and Fischer's Least Significant Difference (LSD) are reported at the bottom of each column. The CV is a percentage that indicates the precision of measurement. Columns with low CV's had lower error between replications within a given treatment. The LSD is used to compare values *within* a column and is the minimum difference between two values for a "real" difference to exist. The alpha level for the LSD in these trials was 0.05 or 5%, which means, we are 95% certain that values differing by more than the LSD are not due to chance. The MCV% is the LSD divided by the mean and the quotient is multiplied by 100 ([LSD/mean]*100). The LSR% is the LSD divided by the range and the quotient is multiplied by 100 (LSD/[high-low]*100).
